

Adolescent and Young Adult hip Reconstruction

Diagnosis

M Al-Maiyah

Mr G De Kiewiet

26/09/2011

Introduction

- The diagnosis of hip pain can be difficult.
- It should be differentiated from low back pain and other pelvic disorders.
- Hip pain could be;
 - Intra-articular
 - Extra-articular
- Diagnosis; history, clinical examination and imaging (Radiographs, CT, MR Arthrogram)

History 1

- Age & Sex, occupation, sports & activity level.
- Onset: Traumatic versus Atraumatic;
trauma history is indicator of good outcome.
- Characteristic features;
 - Mechanical symptoms – better prognostic factor
 - Simple pain with activity- poor prognostic indicator
 - Pain at rest- least likely to respond to joint preserving intervention.

History 2

- Exacerbations & relieving factors
 - Symptoms worse with activities, twisting.
 - Sitting position, uncomfortable (hip flexion).
 - Pain with rising from seated position (catching).
 - Difficulty on stairs.
 - Pain with entering/exiting car.
 - Dyspareunia, especially in women.
 - Difficulty with shoes, socks, etc.

History 3

- Localisation of symptoms;
think Hilton's law
 - Explain why muscle spasm & cutaneous sensations may accompany joint pain
- Classically anterior groin pain, radiating to medial thigh & may knee
 - (mainly L3, contributions from L2-S1)

History 4

- C-sign; characteristic of hip joint pathology.
 - Don't mix with trochanteric bursitis!

History 5

- Posterior hip pain; rare, but can occur
- Past hip problem, injuries
- Previous treatment, non-operative or operative
- Systemic review; GUS, GIT, Neurology, Vascular
- Family history/ social history.

Clinical examination₁

- History  direct physical examination
- Inspection; posture, stance & gait.
- Posture, in standing & seated position;
 - Looking for list, asymmetry.
 - Pelvic obliquity, spinal mal-alignment.
 - Leg length discrepancy.
 - Leg rotation
- **Trendelenberg test**

Clinical examination₂

- Gait:
 - Trendelenburg: Abductor strength, proprioception mechanism.
 - Antalgic: Trauma, fracture, synovial inflammation.
 - Pelvic rotational wink: Intra-articular pathology, hip flexion contracture.
 - Excessive external rotation: Femoral retroversion, increased acetabular anteversion, torsional abnormalities, effusion.
 - Excessive internal rotation: Increased femoral anteverision or acetabular retroversion, torsional abnormalities, effusion
 - Short leg gait: iliotibial band pathology, true/false leg length discrepancy

Clinical examination 3

- Spine Examination:
- Palpation: BE SYSTEMATIC
- Measurement:
 - Leg length
 - Thigh circumference
- Thomas test.
- Hip Range of movements, compare to the other hip.
 - Flexion, Extension, Abduction & Adduction.
 - Check muscle strength!

Clinical examination 4

Rotational hip range of movements;
Flex hip and knee to 90° then internally and externally
rotate the joint

Clinical examination 5

- Special test;
- straight leg raise:
exclude lumbar nerve root irritation.
- Active Straight raise or SLR against resistant,
produce forces several times body weight in hip joint.

Clinical examination 6

- Leg Rolling; most specific for intraarticular pathology (less sensitive)

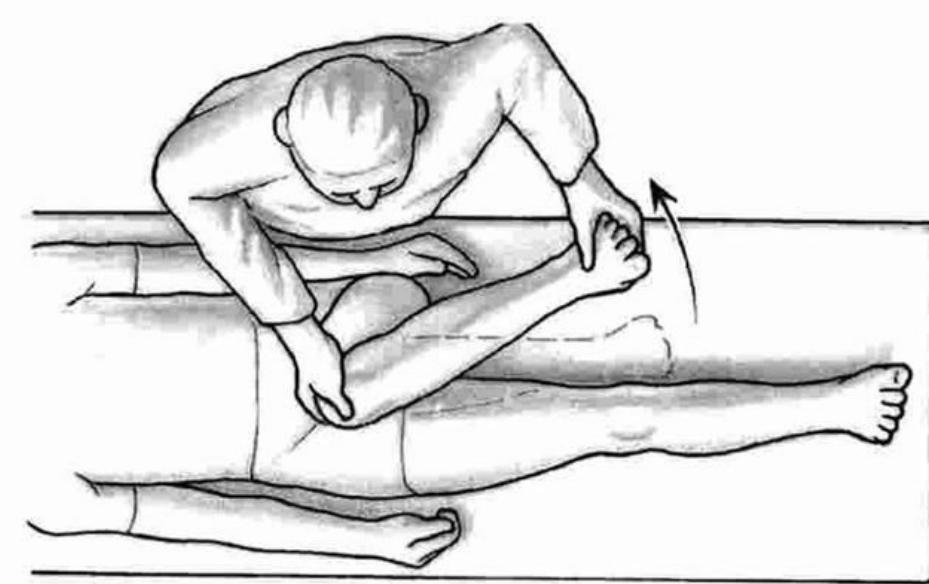

Clinical examination 7

- Patrick or FABER test; Flexion
Abduction External Rotation (Hip or SI joint problem).

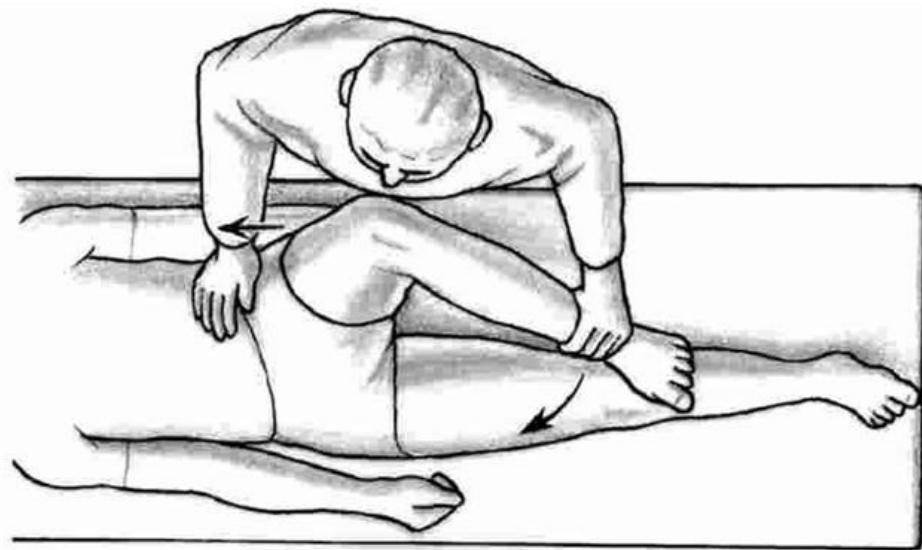

Clinical examination 8

- Impingement test (FADIR); pain with forced flexion and Internal Rotation. The most sensitive test for hip pathology.
 - Produce sharp pain, catch or click.
 - Reproduce patient's symptoms.

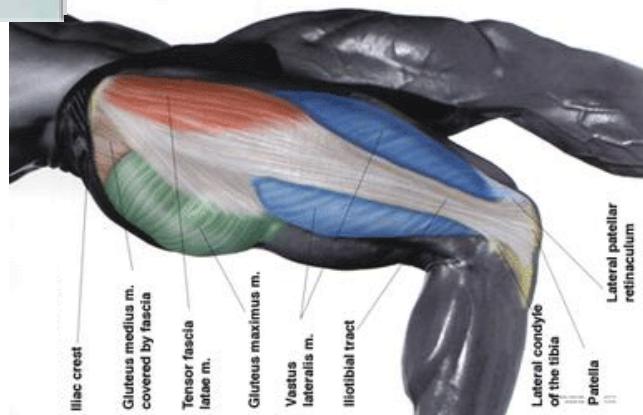

Clinical examination 9

- Reverse Impingement test; pain with flexion and external rotation, might reproduce patient's symptoms.

Clinical examination 10

- “Snapping hip” due to extra-articular cause:
 - Iliopsoas tendonBring hip from flexed, abducted, externally rotated to extension with internal rotation.

Symptoms located laterally
Visible & palpable snap.
